

05 April 2017

1 Overview

Items for which further work was previously requested by one or both of you were as follows:

- Develop a formal model for the impact of reelection on party calls
- Estimate the House models with two party vote share instead of overall vote share
- Summarize readings relevant to this paper
- Continue to rework the paper

William has gone through the process of developing the formal model with me.

Additionally, during this time we discussed the differences between the vote percent variable that we have been using in the House (overall vote percent of candidate) and the Senate (two party vote share). We did not believe that this would cause meaningful differences, but recognize that this is something we want to deal with in some way before sending the paper out for review. Thankfully, the presidential vote share data for Congressional districts also contained this measure, so I have included a section which shows the results when this measure is instead used. I include the tables with these measures in this section in order to provide comparability.

In the section following that, I provide what I consider to be a one sentence summary of the relevant parts of things we are referencing or might reference, with other important points included below this.

Finally, I have made some adjustments to the article draft in the final section.

2 House Tables and Figures with 2 Party Vote Share

As expected moving to two party vote share (rather than total vote share) provides little substantive difference to the results. This also includes a change to how unopposed candidates are scaled. Since Jacobson's data have unopposed candidates vote share as an NA value, rather than set to 100% as in the LEP data, I took William's advice and subtracted the mean from this variable and set it to 0. I include a coefficient plot with the unopposed missing values instead set to 100 without centering the data on 0 to show that this produces essentially no difference. Ultimately our results are robust to these changes and we should simply go with one specification and note that it doesn't matter in the paper or an appendix.

3 Summary of Related Books and Articles

Levitt (1996), “How Do Senators Vote?”

In election years, Senators’ pay more heed to the desires of their state than in the rest of their term.

The methodology of the reelection section is as follows:

- Divides by years, rather than Congresses
- Uses ADA scores of various groups of MCs (both in the House and Senate) as proxies for state, constituency, party
- Uses differences between same-state Senators to get ideology measure (rather than estimate by roll calls or use measures that do)
- The above values are regressed with coefficients constrained to add up to 1 and reported in tables, these are referred to as weights in the utility function
- The weights from an election year are compared with those of Senators 4 or more years from reelection (since the method of comparison is unspecified, I assume it to be a simple comparison such as a paired z -test)

Lee (2009) *Beyond Ideology*

Much of what happens in Congress that is attributed to ideological conflict is actually the result of partisan conflict.

- It is necessary to disentangle party and ideology
- Party brand held to be important to members (no discussion of variation among members)
- Issues are selected in order to put parties in conflict, which is seen as boosting the party brand
- Roll call votes can be a tool for embarrassing the opposition by making them go on record for or against controversial issues
- Greater time between elections in Senate decreases focus on electoral stakes
- Actions taken to benefit the party brand held to be net benefit for members

Carson et al. (2010) “The Electoral Costs of Party Loyalty in Congress”

Voters punish members who are perceived to merely vote the party line.

Canes-Wrone, Brady & Cogan (2002) “Out of Step, Out of Office”

Members who take positions on issues which differ from those of their district are punished by voters.

Theriault (2013) *The Gingrich Senators*

Senators who came from House service with Newt Gingrich brought norms of intense partisan conflict which reshaped the Senate, leading it into a new hyper partisan era.

- Divides post-WWII Senate into 3 eras: Textbook Senate, Individualized Senate, Partisan Senate
- Southern Democrats and Gingrich Senators have each acted as sub-parties at different times; the former brought about compromise, the latter conflict

Smith (2014) *The Senate Syndrome*

The Senate has in recent decades become gridlocked as the result of increased media attention, party polarization, and trends resulting from past rule changes.

4 Paper, Draft 3

4.1 Introduction

Minozzi & Volden (2013) showed that a significant factor in achieving party unity comes not from pressuring moderates but calling on members to coalesce out of shared interest. More extreme members in the party were hypothesized and shown to be the most responsive to the “party call” because they gain the most both from the status of the party and their status as a partisan in most cases. Extreme members who already have strong preferences on an issue would be unlikely to see this preference change, but those whose preferences are weaker will see the call as a clear reason to align for the good of the party.

This paper works to replicate these findings and extend them into Congresses 110-112 in the House as well as into the Senate. This allows us to test the responsive extremists hypothesis in times that the party is thought to be getting more extreme in the House. We can also test if it holds when applied to the Senate in order to see if it is a quirk of the House or a trait of Congressional behavior generally. We hypothesize that these relationships will be largely the same. Further, the inclusion of the Senate allows us to consider the influence of proximity to reelection in choosing whether to heed the call of the party.

Mayhew (1974) shows that reelection is chief among the desires of members of Congress. Canes-Wrone, Brady & Cogan (2002) shows that members who stray too far from the preferences of their district are less likely to be reelected. While this would initially seem to imply that members would act according to the preferences of their district above those of their party, we know from Lee (2009) that the name brands of parties confer advantages on members and that members are thus willing to take actions and positions that are either beneficial to their own party relative to the opposition. and Carson, Koger, Lebo & Young (2010) that following the party line too closely can in itself be electorally costly to an individual member. Levitt (1996) finds that proximity to reelection induces Senators to more strongly take their constituents’ preferences into account. If members only respond to party calls when they do not have strong preferences against the party and proximity to reelection increases the attention they pay to their constituents’ preferences, we should expect that members will be less responsive to party calls in Congresses which they are up for reelection.

4.2 Replication with Extension

In this section we show that the results from Minozzi & Volden (2013) hold when analysis is extended into later Congresses and the Senate. We draw on Congressional roll call data for Congresses 93-112 for both chambers in order to view the behavior of members. As in Minozzi & Volden (2013), we iteratively sort votes based on the predictive power of party in vote decision taken alongside party free ideology. We dub those votes which are significantly predicted by party as party calls and those which are not as noncalls. The set of noncalls from one iteration is used as the votes for calculating party free ideology in the next. A more thorough overview of the original algorithm and the changes we’ve made to it are detailed in an appendix.

We make a number of important findings. First, the relationship between extremism and vote choice is not random with both extremists and moderates of each party likely to

vote against the party on non party call votes, but on party call votes the extremists snap intoline with the party. The relationship we find between ideological extremism and party call responsiveness, shown in figures 1 and 2 demonstrates this as a percent. The nonlinearity between party call response rate and ideological extremism appears to arise from the fact that there is a maximum rate of 100%.

Figure 4: House Rate of Voting With Party by Vote Type

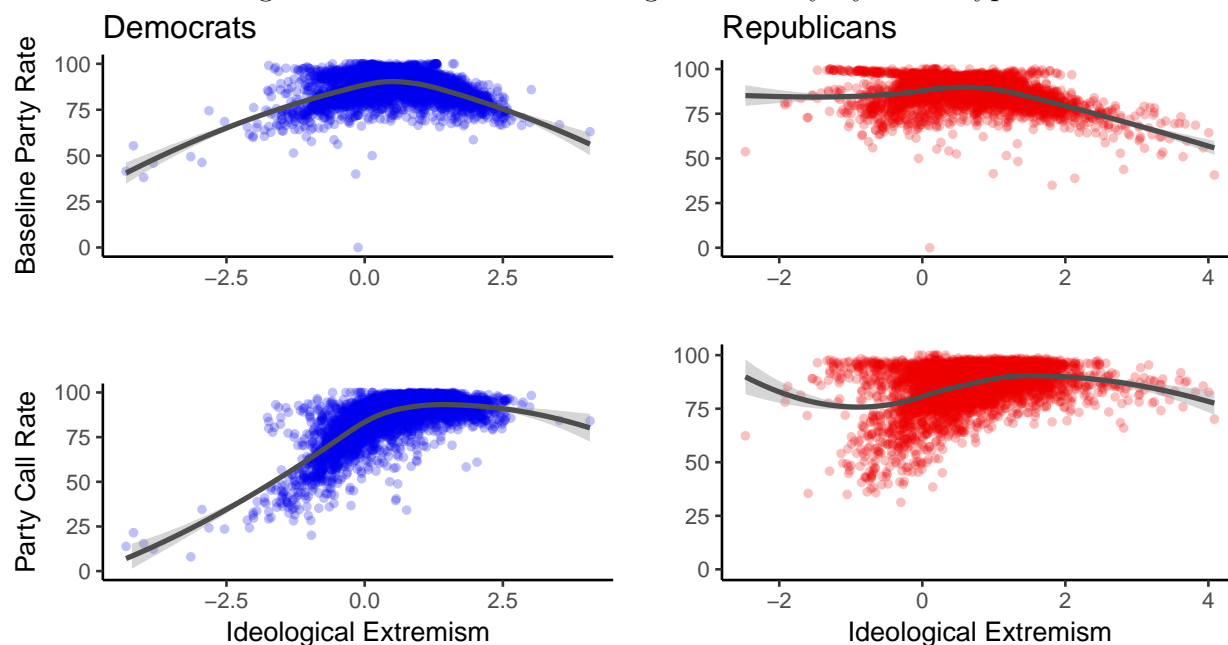

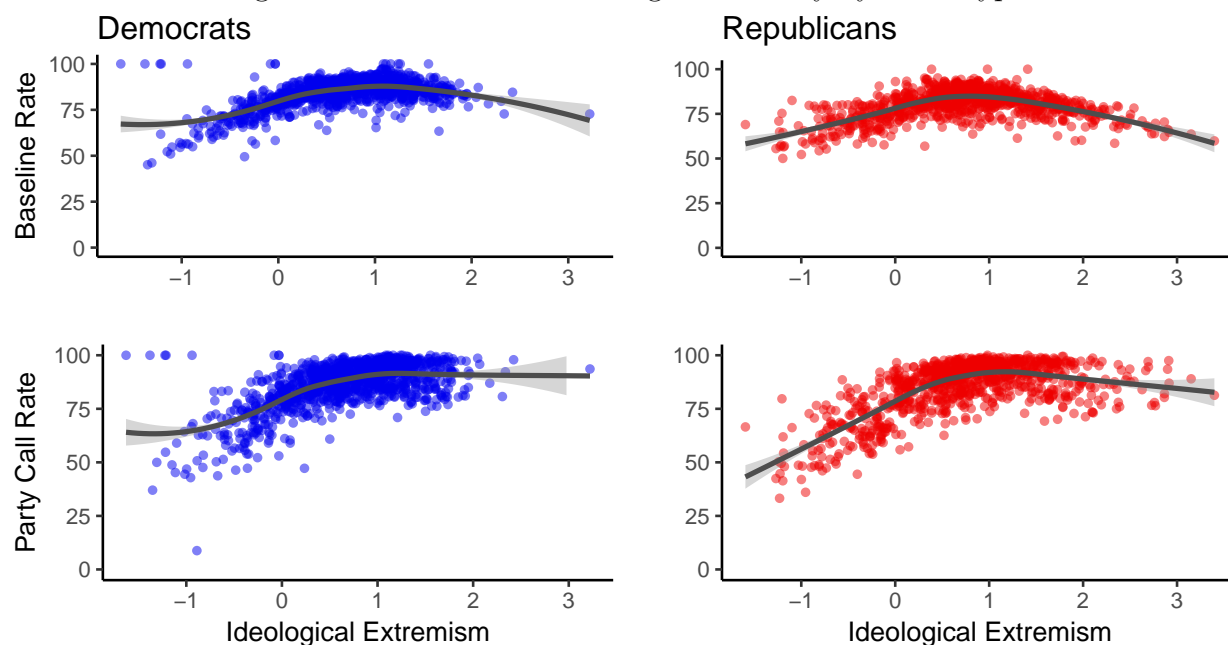

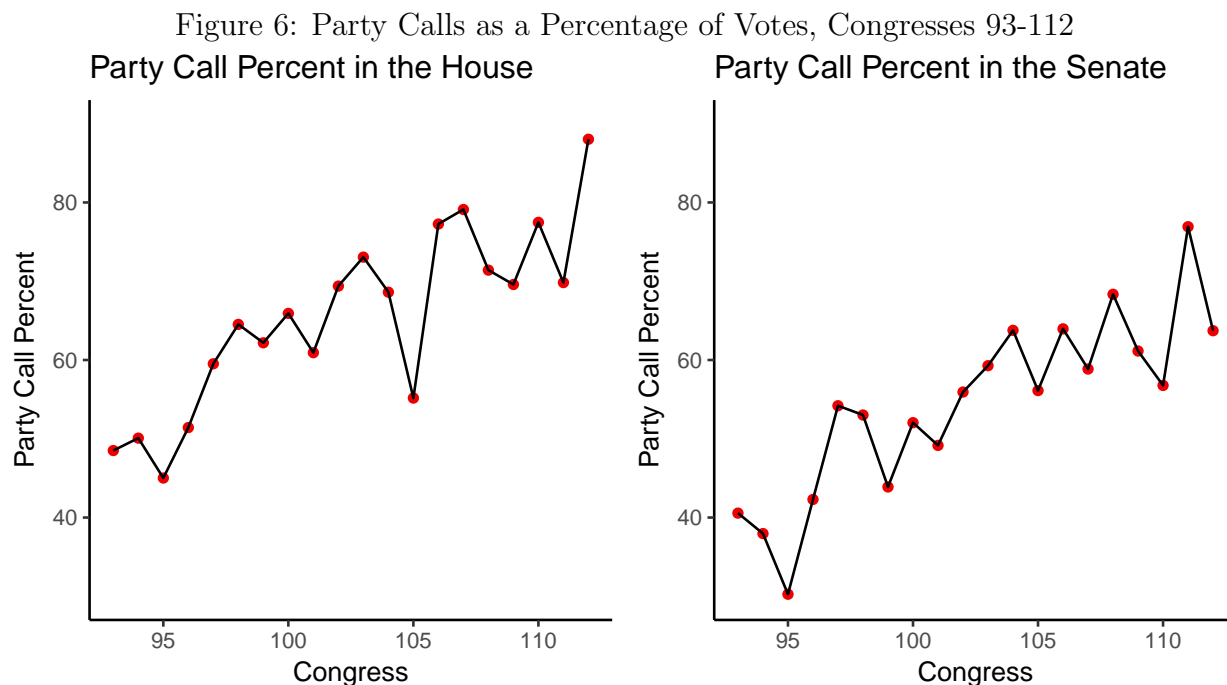

Figure 5: Senate Rate of Voting With Party by Vote Type

We also note that the number of party call votes in both chambers of Congress during the period of analysis are on an upward trend. We believe this trend merits further investigation, but initially take it to echo arguments such as those of Lee (2009), Theriault (2013), and Smith (2014) that Congressional partisan conflict has been on the rise.

Pooled regressions with members divided by party and majority status broadly show similar relationships both between chambers in the current analysis as well as with those presented in Minozzi & Volden (2013). Though they differ in strength between parties, ideological extremism and rate of voting with majority of non party call votes both carry substantive predictive power in determining responsiveness by to party calls.

Unsurprisingly, in both chambers we also find that southern Democrats are less responsive to the party than are other Democrats. We also note that the power committee variable we constructed for the Senate (based on membership in a top 4 committee) carries little predictive power, either in terms of substantive power or statistical significance. This is unsurprising since this is a variable we included less because we believed it had meaning to Senators and more for model comparability. We also note that in both chambers increased same party presidential vote share within one's constituency makes Democrats more likely to respond to a party call but reduces the chances of a Republican doing so.

In Table 2, we see some evidence of differences between members up for reelection and

others. Though it fails to meet traditional significance threshold for Democrats, across all subgroups this coefficient is negative.

4.3 Reelection in the Senate

In this section we estimate models which account for variation within members, using same-state Senator pairs in Congresses which one of them is up for reelection. Such pairings have the advantage of answering to the same constituents. In order to estimate the effect of reelection on member responsiveness we use generalizations of the difference in differences design which compare member responsiveness to the party on party calls, the baseline rate of voting with the party, and the difference between these two quantities along with bootstrapped 95% confidence intervals. For each of these a placebo test with randomly assigned treatment is also shown. These tests is further detailed in an appendix.

Figure 7: Senate Rate of Voting With Party by Vote Type

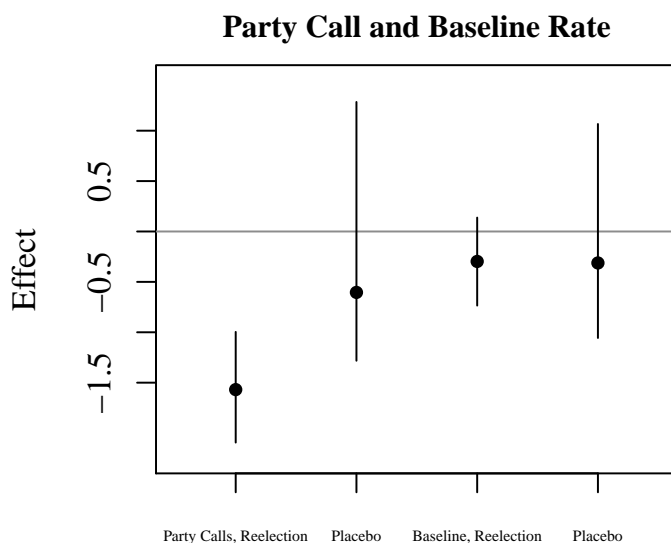

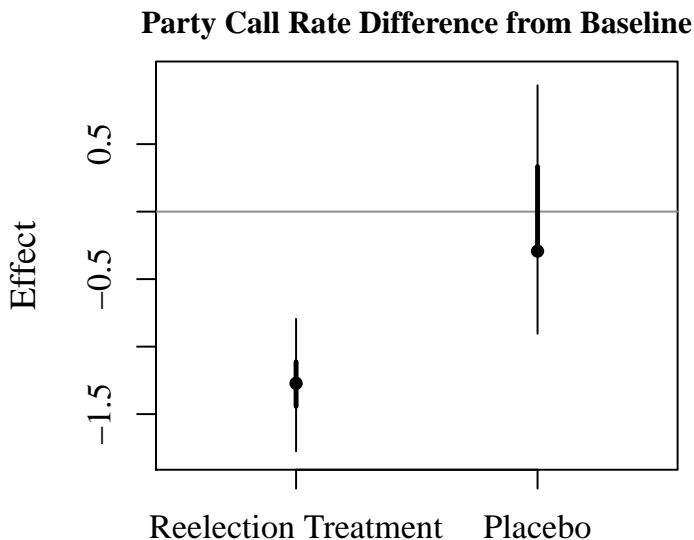

Figure 8: Senate Rate of Voting With Party by Vote Type

These show clearly that member responsiveness to party calls declines by approximately 1.5%. Since the average number of party calls in a Congress during the time we analyze is approximately 365, this means that a Senate party can generally expect to count on members up for reelection for a little over 5 votes against the party on party call votes. Member voting behavior on other votes is negatively signed but fails to meet traditional thresholds of statistical significance and member behavior on party calls when compared to their baseline rate of voting with the party is comparable to that of the changes present in their party call rate generally.

4.4 Conclusion

In this paper, we show that members respond to party calls in the Senate as they do in the House using similar analysis to Minozzi & Volden (2013). Further, in the Senate we are able to consider the role that proximity to reelection has in responsiveness to the party in Congress. This allows us to extend analyses which have focused on behavior in Congress in more general manners and focus in on those areas where differences are most present. Across multiple statistical tests we find that in Congresses which a member is up for reelection there is a lowered responsiveness to the party, especially amongst Republicans.

5 Appendices

5.1 Appendix A: Detailing the New Sorting Algorithm

As in Minozzi & Volden (2013) we develop an algorithm to sort votes based on the degree to which vote choice can be significantly predicted by party when vote choice is modeled by party and ideology. This algorithm works iteratively, with member ideology in one iteration calculated on the votes which were not party calls in the previous iteration, with the ideology for the first iteration being set as votes which have more than 65% or less than 35% of members voting on a bill on the same side. The algorithm must run 15 iterations per Congress as a burn-in period. Once this period has concluded the algorithm continues either until the number of votes switched has hit a minimum and begun to climb or until there are fewer than 5 votes which switch between iterations. Once these conditions are met, it continues for 15 additional iterations, the last 5 of which are used to identify party calls and non calls. Any votes which switched between party calls and non party calls during the final five iterations are dropped from our analyses.

We find that the results produced by the algorithm largely do not involve a tradeoff of party and ideology explaining votes, but instead typically have both explaining effects in the same direction. We have made some changes to this algorithm, which are detailed below.

Table 7: House Sorting Algorithm Coefficient Signs

	(-) Ideal	(+) Ideal
(-) Party	0.38	0.15
(+) Party	0.17	0.30

Table 8: Senate Sorting Algorithm Coefficient Signs

	(-) Ideal	(+) Ideal
(-) Party	0.33	0.16
(+) Party	0.23	0.28

One of the key changes was the use of the `emIRT()` R function as described in Imai, Lo & Olmsted (2016) in order to obtain members' party free ideology. This function was developed by Imai and co-authors in order to produce estimates analagous to those of the `ideal()` function developed by Clinton, Jackman & Rivers (2004), which was used by Minozzi & Volden (2013). A key advantage of this new function for estimation of member ideology is that it produces results with greatly reduced computation.

We found that the lowered number of both members and bills in the Senate required a few changes to the vote sorting method. First, since p-values will necessarily be lower with fewer observations, we had to change the p-value threshold for party significance to 0.05 (from 0.01). Next, since the ideal point algorithm uses a logistic regression problems arose in vote sorting when we also tried to use a logistic regression in the Senate and changed to using a linear model. Neither change leads the sorting in the House to change drastically

and we find that the sorting of votes based on whether they are close or lopsided mirrors that found in Minozzi & Volden (2013) very closely.

Table 9: House Vote Coding for Close and Lopsided Votes

	Party Call	Noncall
Lopsided	4245	6123
Close	9308	1090

Table 10: Senate Vote Coding for Close and Lopsided Votes

	Party Call	Noncall
Lopsided	2063	4876
Close	5233	1851

5.2 Appendix B: Methodology for Senate Reelection Section

In order to better test the role of reelection we use same-state senators as a natural pairing. We view this as an ideal pairing since they answer to the same possible set of voters and therefore should have similar preferences induced by proximity to reelection. The tests we performed on these pairs were generalizations of the difference in differences design in which the member not up for reelection had their response rate subtracted from that of the member who was up for reelection for the first figure in the paper and for the second members had the difference between their party call response rate and baseline rate of voting with the party subtracted from that of the other Senator from their state under the same conditions.

Here we show the effects in tables, along with breakdowns by seat pair type. We additionally show the results of a model with fixed effects by member and Congress. This produces substantively similar effects to those reported in the main paper on the effects of being up for reelection and changes in ideological extremism. This is presented as a robustness check for the results we present in the paper.
